Fig. S1. Sakata & Nagao et al.

Fig. S1. Targeting scheme for generating the *Xist*^{CAG⁴5'} allele

(A) Genomic fragment containing the endogenous *Xist* promoter and the 5' region of exon 1 (-912 nt) was replaced with a CAG-Pac ECFP-pA cassette to produce the *Xist*^{CAG⁴5'-2L} allele. In the presence of cre recombinase, the *Xist*^{CAG⁴5'-2L} allele is converted into *Xist*^{CAG⁴5'}.

(B) Homologous recombination was confirmed by Southern blotting. RCA2.344 harbored the correct targeting event. Genomic DNA of RCA2.344 and parental R1 was digested with either *Hind*III (left) or *Bg*II (right), transferred onto a nylon membrane, and probed with either PE0.24 (left) or XXh0.7 (right) (Sado, *et al.*, 2005).

(C) Germline transmission of *Xist*^{CAG⁴5'-2L} was confirmed by Southern blotting. Southern blot containing tail DNA digested with *Xba*I was probed with XB (Ohhata, *et al.*, 2008).

(D) Selective loss of female embryos carrying the paternal *Xist*^{CAG⁴5'} allele. No female pups were born upon paternal transmission of *Xist*^{CAG⁴5'}, strongly suggesting that imprinted X-inactivation was compromised in female embryos.

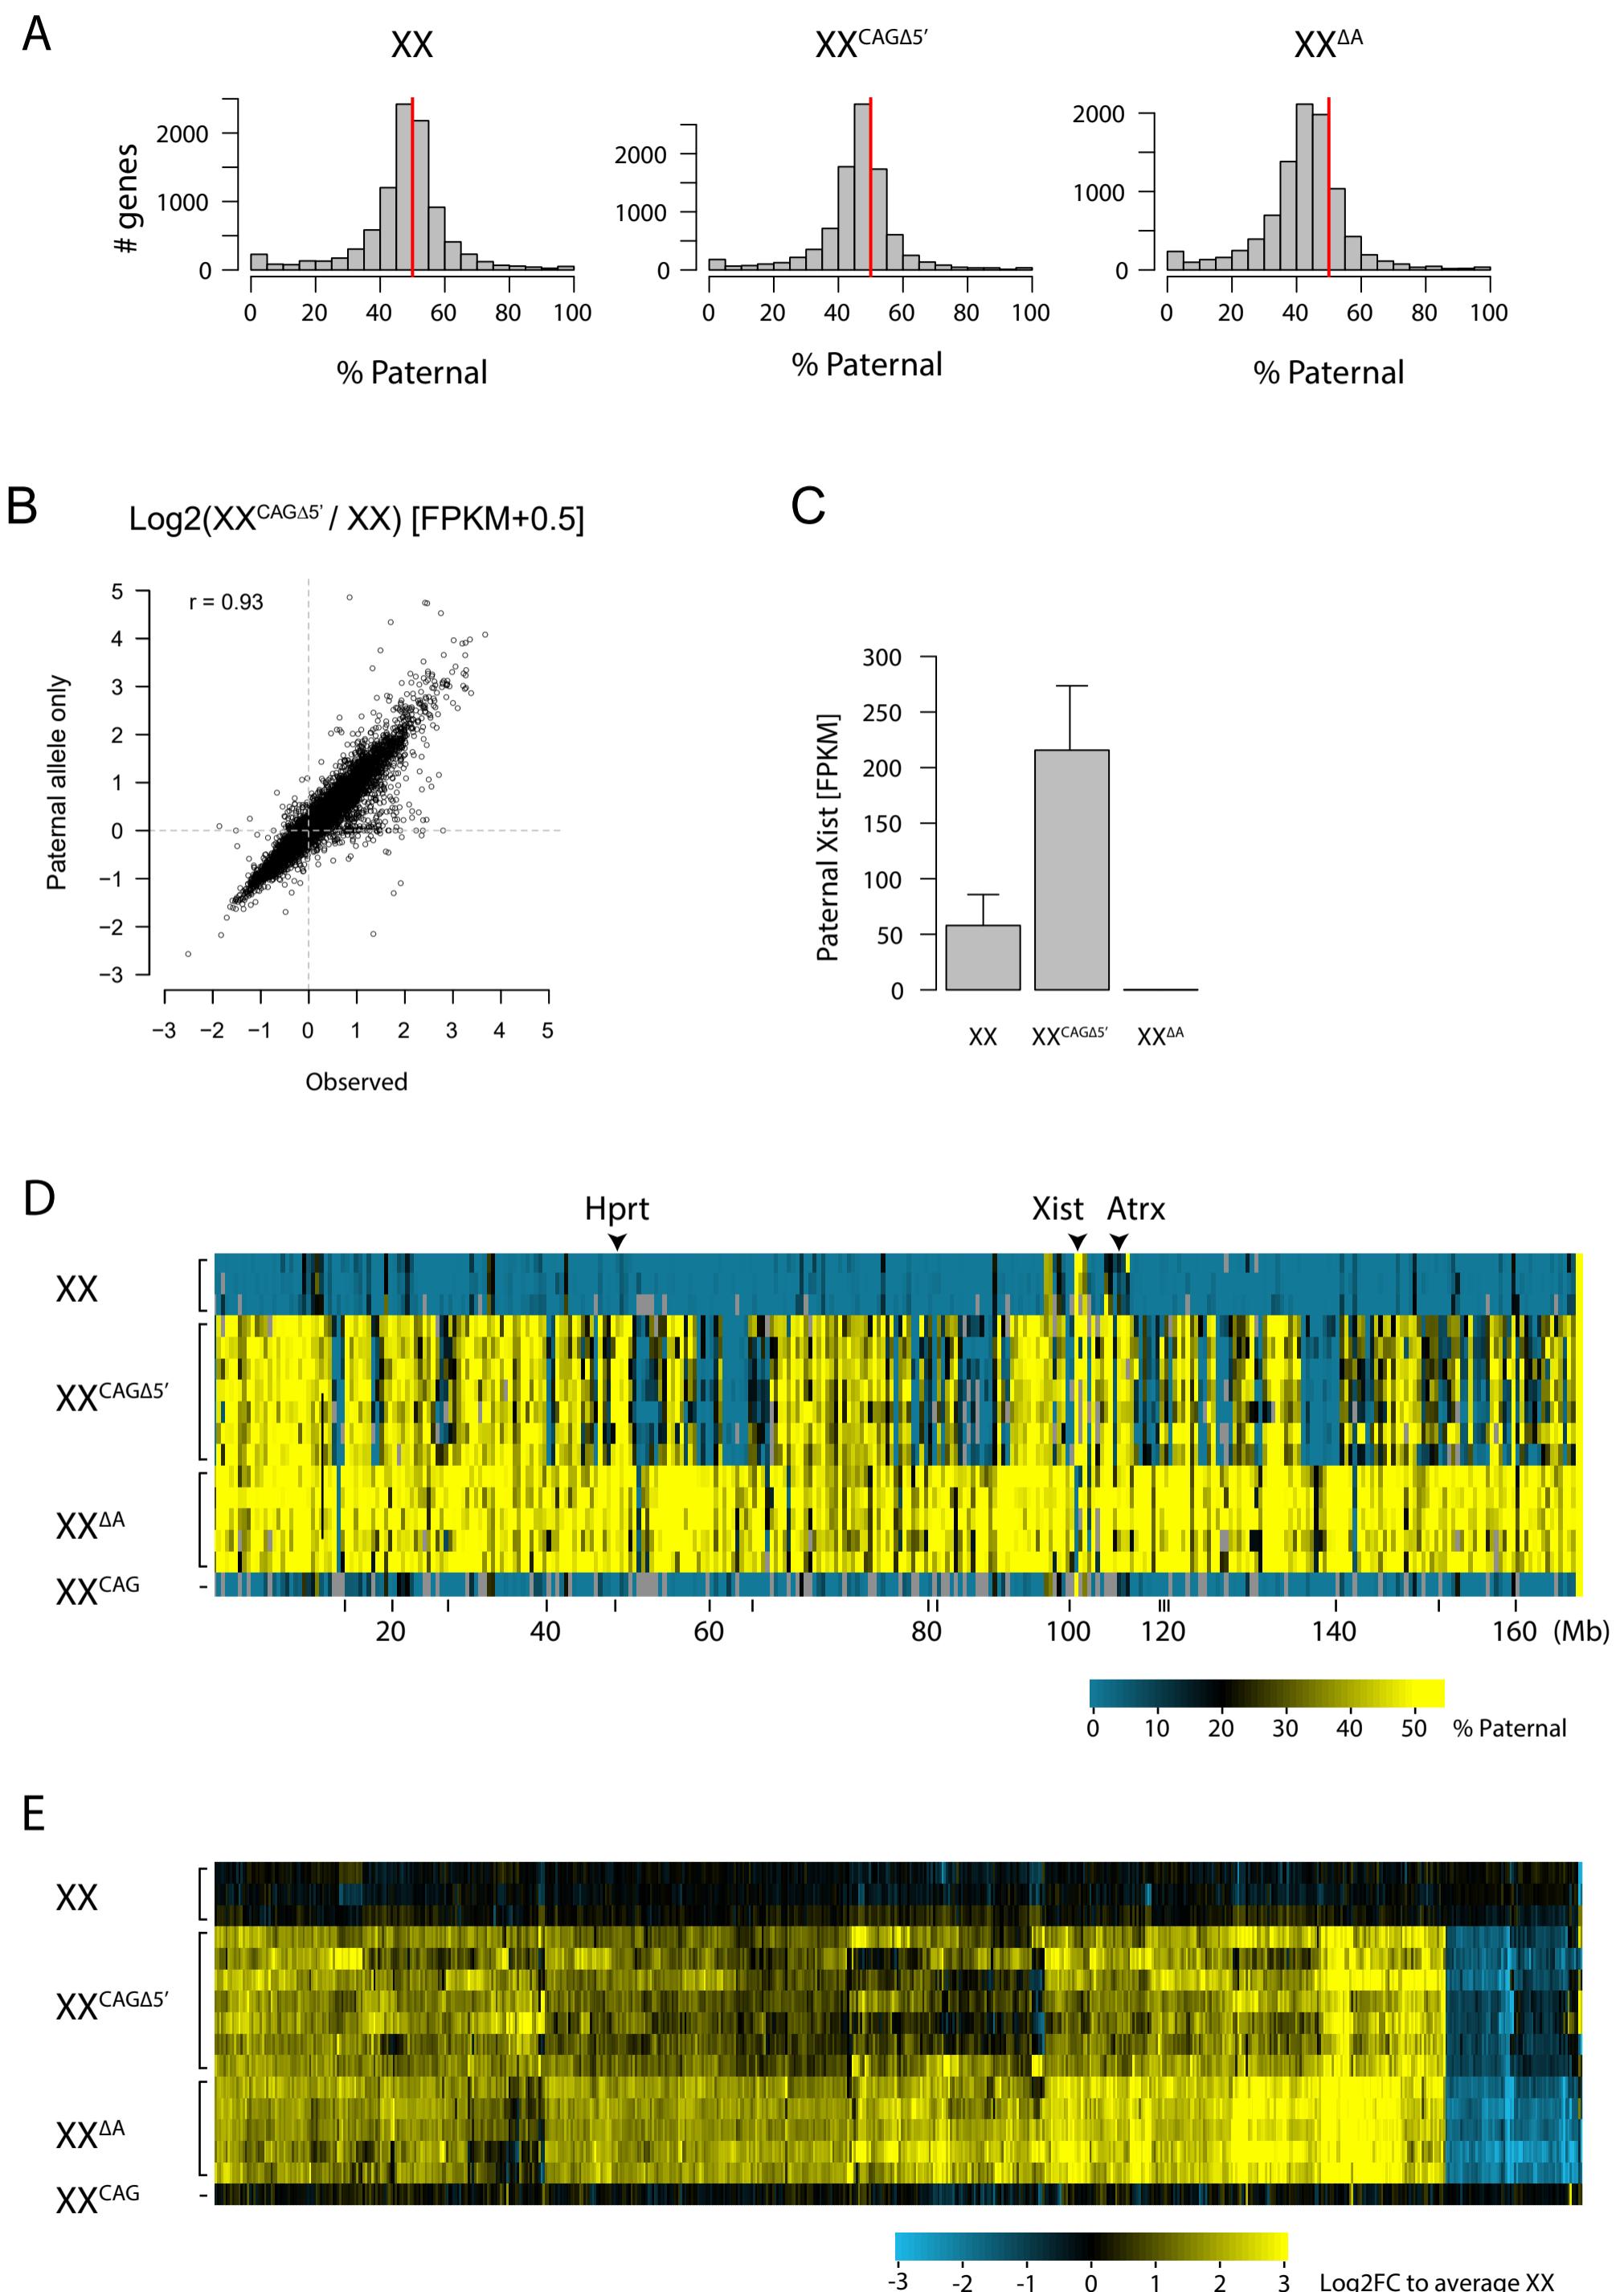

Fig. S2. Sakata & Nagao et al.

Fig. S2. Expression profile of X-linked and autosomal genes in in XX^{CAGΔ5'} and XX^{ΔA} in comparison with XX.

(A), (B) Most of the autosomal genes are biallelically expressed in the wild-type, XX^{CAGΔ5'} and XX^{ΔA} trophoblast. (A) Given that the mode of % paternal distribution among autosomal genes is slightly below 50% in XX^{CAGΔ5'} and XX^{ΔA}, it is likely that the maternal decidual tissues are contaminated in the trophoblast of both types of mutants. Since the majority of autosomal genes are expected to be equally expressed both among tissues and between alleles, we estimated that proportion of the maternal contamination in XX, XX^{CAGΔ5'} and XX^{ΔA} are 0%, 5.2%, and 11.2%, respectively. (B) However, when the expression of the paternal copies, which could be identified only in the trophoblast, is extracted and plotted against the observed overall expression ratios of autosomal genes in XX^{CAGΔ5'} relative to XX, the majority of misregulated genes exhibit a similar trend of changes as shown in Fig. 4F. This indicates that such maternal contamination would not affect our conclusion.

(C) Expression levels of paternal *Xist* in each genotype are plotted as mean with standard deviation.

(D) Comparison of % paternal reads of the 319 genes in all the individual trophoblast analyzed with their position along the X chromosome.

(E) Heat map comparing the expression levels of the 1,277 autosomal genes shown in red in Figure 4F. Genes were aligned so that those show similar kinetics of the changes in their expression levels.

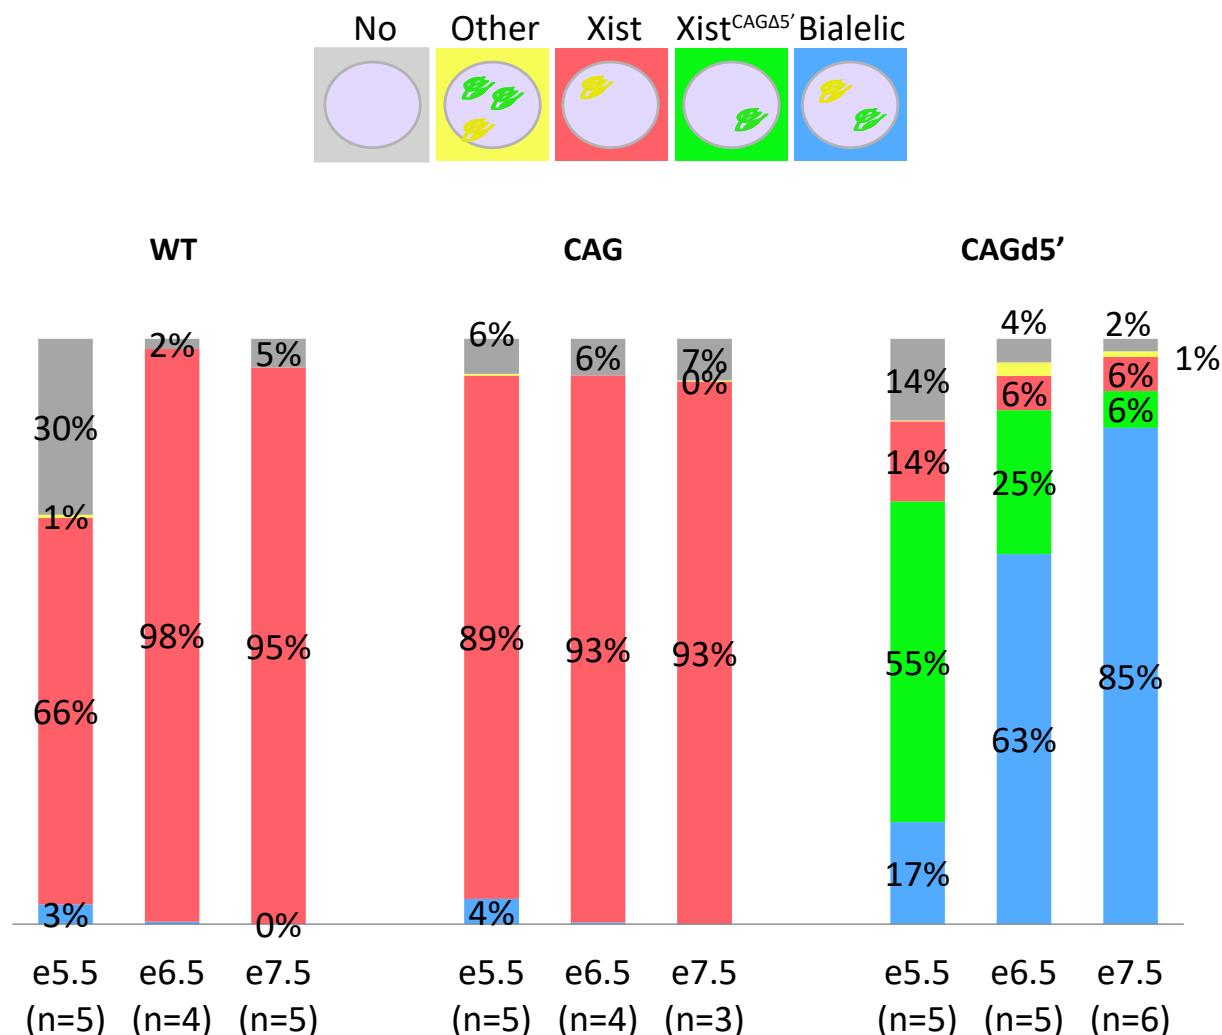

Fig. S3. Sakata & Nagao et al.

Fig. S3. Comparison of expression patterns of *Xist* in the embryonic tissue among respective genotypes at early postimplantation stages.

Cells in the distal part of the embryo recovered from E5.5 to E7.5 were classified according to their expression patterns of *Xist* in respective genotype. While cells expressing either wild-type or mutated *Xist* RNA are both observed in XX^{CAGΔ5'}, the population of those cells with biallelic expression increases over time. One reason why the prevalence of cells with a single mutant *Xist* cloud is higher than that of cells with a single wild-type *Xist* cloud could be ascribed to the fact that we did not remove the visceral endoderm, in which the mutated *Xist* allele is exclusively expressed due to imprinted X inactivation, from the distal part of the embryos enriched with the epiblast. Each Color of bar graphs matches that of rectangles showing respective patterns of *Xist* expression. Yellow *Xist* cloud, wild-type *Xist* RNA; green *Xist* cloud, *Xist*^{CAGΔ5'} RNA; n, the number of embryos examined.
