

Development

Cover: The planarian p53 homolog is predominantly expressed in the immediate postmitotic progeny of stem cells (green) and little, if at all, in dividing stem cells (magenta). Functional studies demonstrate that the roles of p53 in regulating stem cell proliferation and self-renewal are not specific vertebrate innovations, but have much more evolutionarily ancestral origins. See Development and Stem Cells Research article by Pearson and Sánchez Alvarado on p. 213.

A key innovation in the evolution of flowering plants is their reduced female gametophyte, comprising only seven cells. Sundaresan and Alandete-Saez review recent advances in our understanding of the patterning, evolution and maternal effects of this enigmatic structure. See Review on p. 179.
